
3.1.1 Disease may be caused by infectious pathogens or may reflect the effects of lifestyle.

Pathogens	Pathogens include bacteria, viruses and fungi. Disease can result from pathogenic microorganisms penetrating any of an organism's interfaces with the environment. These interfaces include the digestive and gas-exchange systems. Pathogens cause disease by damaging the cells of the host and by producing toxins.
Lifestyle	Lifestyle can affect human health. Specific risk factors are associated with cancer and coronary heart disease. Changes in lifestyle may also be associated with a reduced risk of contracting these conditions. Candidates should be able to • analyse and interpret data associated with specific risk factors and the incidence of disease • recognise correlations and causal relationships.
