

5.2 A drainage basin is an open system within the global hydrological cycle.	a. A drainage basin is a system of linked processes: inputs (precipitation patterns), flows (interception, infiltration, direct runoff, saturated overland flow, throughflow, percolation, groundwater flow) and outputs (evaporation, transpiration and channel flow).
	b. Physical factors within drainage basins determine the relative importance of inputs, flows and outputs (climate, soils, vegetation, geology, relief).
	c. Humans disrupt the drainage basin cycle by accelerating processes (deforestation, changing land use) and creating new water storage reservoirs or by abstracting water. (🌐 Amazonia)
