

6. Transformations using matrices

What students need to learn:

Linear transformations of column vectors in two dimensions and their matrix representation.

The transformation represented by $\mathbf{AB}$ is the transformation represented by $\mathbf{B}$ followed by the transformation represented by $\mathbf{A}$.

Applications of 2×2 matrices to represent geometrical transformations.

Identification and use of the matrix representation of single transformations from: reflection in coordinate axes and lines $y = \pm x$, rotation through any angle about $(0, 0)$, stretches parallel to the x -axis and y -axis, and enlargement about centre $(0, 0)$, with scale factor k , ($k \neq 0$), where $k \in \mathbb{R}$.

Combinations of transformations.

Identification and use of the matrix representation of combined transformations.

The inverse (when it exists) of a given transformation or combination of transformations.

Idea of the determinant as an area scale factor in transformations.
