

(c) Population and sampling

Students should be taught to:

understand the meaning of the term population;

understand the word census, especially with regard to well defined, small scale and large populations, eg National census;

understand the reasons for sampling and that sample data is used to estimate values in the population;

understand the terms random, randomness and random sample;

generate and use random numbers using a random number table, calculator or computer including the use of a spreadsheet;

understand, design and use a sampling frame;

be able to select a simple random sample or a stratified sample by **more than** one category as a method of investigating a population;

have a basic idea of the concept of bias, how it might occur in a sampling procedure and how it might be minimised;

understand and use systematic, quota and cluster sampling;

understand the strengths and weaknesses of various sampling methods, including bias, influences and convenience.

The definition of 'population' can vary – eg it could be a family or the cars in a car park.

A census obtains information about every member of a population. **The types of questions used and how the collected data is used.**

Reasons to include time and efficiency, and the impossibility of reaching the whole population in many circumstances.

The relation between 'random' and 'equally likely' may be tested.

Designing a sampling frame might be tested.

An appreciation of an appropriate sample size will be expected, as will the ability to make a random selection or sample from a population using tables of random numbers or a calculator.

Examples of one category might include male/female or KS2/KS3/KS4.

Possible bias in sources of secondary data, eg vested interests.

With particular reference to large scale lines of enquiry such as quality control or opinion polls.

An awareness of influences such as gender, social background or geographical area will be expected.
